

Besufkad Gym Club Membership System

CoSc3091 — Web Programming · Individual Assignment I · 29 September 2026

Student: Besufkad Deneke
Department: Computer Science

Student ID: 006/2016
Project: Gym membership and payment receipt verification

1. Overview

This responsive PHP/MySQL application presents a gym’s branches and membership packages. Visitors can register and sign in; members can create a membership plan by selecting its package, exercise focus, branch, start date, duration, and payment method. Plans and enquiries are persisted in MySQL. Each booking has a unique payment reference, and members can submit the transaction code from their receipt for manual administrator comparison. A submitted code does not automatically prove payment; the plan stays pending until verified.

2. Implemented features

- Home, About, Membership, Contact, Register, Login, Dashboard, and Logout pages with shared navigation.
- Responsive CSS using Grid, Flexbox, and mobile breakpoints; light/dark theme toggle.
- Validated registration, unique username/email checks, password hashing, session login, and logout.
- Protected dashboard with database-backed membership plans and computed monthly totals/end dates.
- Unique per-booking payment reference, receipt transaction-code submission, and pending verification status.
- Upcoming membership listing and cancellation; contact messages persisted in MySQL.
- Prepared statements, server-side validation, CSRF tokens, escaped page output, and popup feedback.

3. Database design

The schema in **database.sql** defines four tables. Bookings link to users and plans by foreign keys; plan prices are read from the plans table.

Table	Purpose and key links
users	Member profile, unique email/username, password hash.
plans	Package name, monthly price, duration, description.
bookings	User and plan foreign keys; branch, membership dates, focus, months, total, payment state, unique reference, submitted receipt transaction code.
messages	Contact form submissions.

Passwords are stored using PHP password hashing. The contact messages table is independent and records enquiries.

Entity relationship diagram

4. Validation and evidence

PHP syntax was checked across the application; JavaScript syntax was checked with Node.js. Browser testing covered registration, sign-in, payment-method account popup, membership submission, plan foreign-key persistence, receipt-code submission, and cancellation. MySQL queries confirmed test bookings and transaction codes were stored; temporary test data was removed afterward.

Home — landing page and navigation

About me — name, ID, department and bio

Membership — monthly packages

Dashboard — payment and receipt-code workflow

Register — new member form

Contact — inquiry form

5. Individual contribution

Draft—confirm that it accurately reflects your work: I, Besufkad Deneke, designed and implemented the Besufkad Gym Club Membership System for the CoSc3091 individual assignment. My work includes the responsive multi-page interface, PHP registration and session-based authentication, relational MySQL schema and prepared-statement integration, membership and receipt-code workflow, input validation, testing, and documentation.

Confirm/edit this contribution statement so it accurately describes your individual work.

6. Submission notes

The repository README describes local PHP/MySQL setup and test-account creation. There is no pre-seeded member login: evaluators register through the site. No live deployment is configured; the local run instructions are provided.
