

1. Project overview

The Besufkad Gym Club Membership System is a responsive website for a fictional gym with branches in Addis Ababa. Visitors can review the gym and membership options, register and sign in, and send a contact enquiry. Signed-in members can create a membership plan by selecting a package, training focus, branch, start date, duration, and payment method. Each membership is saved in MySQL and receives a unique payment reference. Members can submit the transaction code printed on their payment receipt so the gym can manually compare it with its payment records.

Payment is not processed automatically. A submitted transaction code does not itself prove payment; the membership remains pending until the administrator confirms the receipt.

2. Main features

- Seven linked pages: Home, About, Membership, Contact, Register, Login, and member Dashboard; logout is also available to signed-in members.
- English and Amharic language switch with translated navigation and core page content.
- Responsive navigation and layouts using CSS Grid, Flexbox, and mobile breakpoints; light/dark theme toggle.
- Registration with required-field, email, username, and password validation, duplicate checks, and password hashing.
- Session-based authentication, protected dashboard, and logout confirmation.
- Database-backed membership creation, branch/focus selection, duration calculation, unique payment reference, and future-plan cancellation.
- Per-membership payment receipt transaction-code submission for manual verification.
- Contact form messages persisted in the database.
- CSRF tokens on forms, MySQLi prepared statements, and HTML output escaping.

3. Database design

The schema is defined in `database.sql`. It contains four tables:

Table	Purpose	Key relationships
users	Member profile and password hash	One user can own many bookings
plans	Membership plan name, monthly price, duration, and description	One plan can be referenced by many bookings
bookings	Membership selection, dates, price, payment status, reference, and transaction code	Foreign keys to users and plans
messages	Contact form submissions	Independent enquiry records

4. Implementation and testing

The application uses HTML5 semantic page structure, shared PHP header/footer includes, external CSS and JavaScript, PHP sessions, prepared statements, and server-side validation. Validation performed during development included PHP syntax checks, JavaScript syntax checks, browser checks for registration, sign-in, payment flow, and cancellation, plus MySQL checks confirming bookings and transaction codes persist in the database.

5. Individual contribution

I, Besufkad Deneke, developed the Besufkad Gym Club Membership System for the CoSc3091 individual assignment. My contribution includes the responsive multilingual website, PHP registration and session-based authentication, MySQL schema and prepared-statement integration, membership booking and payment reference workflow, receipt transaction-code submission, validation, testing, and project documentation.

6. Submission files

The project source, database export, README, screenshots, ER diagram, and report are included in the submission ZIP. The public repository contains the same project source and documentation.
